3) a)

Because $\tilde{x}_i - \tilde{x}_i$ should be parallel to \tilde{n} , we can say that:

$$\tilde{x}_i - \tilde{x}_i = ((\tilde{x}_i - \tilde{m})^T \tilde{n}) \tilde{n}$$

Solving this equation, we get:

$$\tilde{x}_i = \tilde{x}_i - ((\tilde{x}_i - \tilde{m})^T \tilde{n}) \tilde{n}$$

b) We have to minimise the sum of the ^{squares of} Euclidean distances between each data point \tilde{x}_i & \tilde{x}_i . Let us call this sum S .

$$S = \sum_{i=1}^N \|\tilde{x}_i - \tilde{x}_i\|_2^2$$

Substituting the expression from part a), we get

$$S = \sum_{i=1}^N \|(\underline{x}_i - \underline{m})^T \underline{n}\|_2^2$$

$$S = \sum_{i=1}^N \|[(\underline{x}_i - \underline{m})^T \underline{n}]\|^2 \cdot \|\underline{n}\|_2^2 \quad \left[\begin{array}{l} \text{Because } (\underline{x}_i - \underline{m})^T \underline{n} \text{ is a} \\ \text{scalar} \end{array} \right]$$

$$= \sum_{i=1}^N [(\underline{x}_i - \underline{m})^T \underline{n}]^2 \quad \left[\begin{array}{l} \text{Because } \underline{n} \text{ is a unit vector} \end{array} \right]$$

Because we know that the optimal \underline{m} is \underline{m}^* , we can replace \underline{m} with \underline{m}^* .

$$\therefore S = \sum_{i=1}^N [(\underline{x}_i - \underline{m}^*)^T \underline{n}]^2$$

c) Let \underline{q} be the unit direction vector of \mathbb{L} . \underline{q} will be orthogonal to \underline{n} . Hence, \underline{q} and \underline{n} will form a basis for \mathbb{R}^2 .

The projection matrix onto the line's direction is $\underline{q}\underline{q}^T$. Similarly, the projection matrix onto \underline{n} 's direction is $\underline{n}\underline{n}^T$.

Because $\begin{array}{l} \text{Projection matrix} \\ \text{of } \underline{q} \end{array} + \begin{array}{l} \text{Projection matrix} \\ \text{of } \underline{n} \end{array} = \text{Identity matrix}$

$$\underline{q}\underline{q}^T + \underline{n}\underline{n}^T = \underline{I}$$

Let us get back to the minimisation problem: we want to minimise S , where:

$$S = \sum_{i=0}^N \left[(x_i - m^*)^T n \right]^2$$

To simplify this expression, let us take $y_i = x_i - m^*$. Then:

$$S = \sum_{i=0}^N (y_i^T n)^2$$

We can see that this summation is the squared Frobenius norm of Xnn^T where:

$$X = \begin{bmatrix} -y_0^T - \\ \vdots \\ -y_N^T - \end{bmatrix}$$

Hence, S can be further simplified: $S = \|Xnn^T\|_F^2$

Because we know that $nn^T = I - qy^T$,

$$\begin{aligned} S &= \|X(I - qy^T)\|_F^2 \\ &= \|X\|_F^2 - \|Xq\|_F^2 \end{aligned}$$

Because $\|X\|_F^2$ is a constant we have to minimise $\|Xq\|_F^2$ so that S is minimised. For this we shall have to find a q s.t. $\|Xq\|_F^2$ is minimised.

d) Because we know that the maximum value of $\|\tilde{X}g\|_F^2$ occurs when g is the eigen vector corresponding to the largest eigenvalue of \tilde{X} .

Furthermore, the minimum value of $\|\tilde{X}g\|_F^2$ will be equal to this largest eigenvalue.

If we perform on SVD on \tilde{X} , we know that:

→ The largest eigenvalue will be σ_1^2 (square of largest singular value)

→ $\tilde{g} = \tilde{v}_1$, where \tilde{v}_1 is the largest principal component

Hence, the problem is now reduced to finding the best 1-rank approximation for \tilde{X} . We know, from the Eckart-Young theorem, that the best way to do this is to perform a low rank approximation.

The one-rank approximation of $\tilde{X} = \tilde{u}_1 \sigma_1 \tilde{v}_1^T$

Because σ_1 is a scalar, $\tilde{X} = \sigma_1 \tilde{u}_1 \tilde{v}_1^T$

We can also see that the unit vector of the line, $\tilde{g} = \tilde{v}_1$.

Because \tilde{V}^T is an orthogonal matrix, \tilde{v}_1 & \tilde{v}_2 are orthogonal to each other. Also, because we know that $\tilde{g} = \tilde{v}_1$, \tilde{v}_1 must be equal to \tilde{g} .

In other words, $\tilde{V}^T = \begin{bmatrix} 1 & 1 \\ \tilde{g} & \tilde{n} \\ 1 & 1 \end{bmatrix}$

e) To get the equation of the best fit line, we need a point on the line. We also shall require a unit normal vector to the line.

→ we have \underline{m}^* as the point on the line.

→ we have \underline{n} is the unit normal vector. We may use \underline{v}_2^T also.

Hence, the equation for the best fit line is:

$$\underline{L} = \underline{n} (\underline{x}_i - \underline{m}^*)$$
